

10 Matapouri

Description and geomorphology

Matapouri is an east facing pocket beach located approximately 25 km north-east of Whangarei.

The Matapouri site includes a barrier spit shoreline that has both an open coast and estuary shoreline. The open coast shoreline is approximately 1 km long.

The beach comprises fine to medium sand and has a minimal high tide berm that is less than 5 m wide.

The site has a healthy dune system at the northern end of the site which is well vegetated with spinifex. The dune elevation ranges from RL 4 to 7 m. A recent erosion scarp is evident near the centre of the bay where the dune face is over steep.

The site has a large intertidal flat area located at the southern end of the site located adjacent to the river mouth. This area is a local sediment sink. The shoreline along the estuary side of the spit is relatively low lying and erosion protection structures are present along most of the shoreline.

The north facing estuary shoreline located on the opposite side of the channel appears to be building out significantly.

Local considerations

A small stream enters the site at the northern extent. The stream has a local effect on shoreline position.

Dune nourishment has been undertaken at the site primarily focussed on placing sand sourced from the estuary along the centre of the site.

There are no erosion protection structures located on the open coast section of the site. However, we understand some sections of a failed rock revetment remain, buried under subsequent dune nourishment works. The south facing estuary shoreline has a range of erosion protection structures in relatively poor condition.

Site Photograph C (estuary – north facing shoreline)

Coastal Erosion Hazard Assessment

The site is split into seven cells based on differences in geomorphology, dune height and shoreline movement trends.

Adopted component values are presented within Table 10-1. Short-term erosion values on the open coast range from 10 to 30 m and within the estuary between 2 and 6 m except for Cell F which is more variable and is assigned a value of 5 to 20 m. Shoreline trends are variable on the open coast at between -0.2 and +0.2 m/year and generally erosive within the estuary at 0 to -0.2 m/year, except for Cell F which had accreted significantly (up to 85 m) since 1942.

Histograms of individual components and resultant CEHZ distances using a Monte Carlo technique are shown in Figure 10-1 to Figure 10-7.

Coastal Erosion Hazard Zone widths are presented within Table 10-2 to 10-4 and Figure 10-8. CEHZ1 values are between 12 and 27 m, CEHZ2 values are between 28 and 60 m and CEHZ3 values are between 34 and 68 m. CEHZ's have been mapped in agreement with the calculated values, although where CEHZs from the sea and estuary intersect at the distal tip of the sand spit, the hazard zone has been truncated. Note that cell 10F has accreted since about 1942, with CEHZs offset from the accreted most recent shoreline.

Figure 10-9 shows the available historic shorelines for Matapouri.
